

Strategic Leadership in Corporate Social Responsibility

June 2022

Abstract. We propose a strategic theory of Corporate Social Responsibility (CSR). Shareholder maximizers commit to a mission statement that extends beyond firm value maximization. This commitment leads firms to change their actions in ways that ultimately favor shareholders. We thus provide a formal analysis of the “doing well by doing good” adage in an industry setting where firms act strategically. We also provide conditions such that the industry game we study has the nature of a pure coordination game. Our framework thus provides a natural and novel theory of strategic leadership in CSR. By selecting a CSR mission statement, a first mover leads the industry to a Pareto optimal equilibrium.

Keywords: Leadership, corporate social responsibility, shareholder model, stakeholder model, externalities, mission statement, clean-energy technology, supply chain, wage setting, commitment.

1. Introduction

Why do corporations, in particular public corporations, adopt corporate social responsibility (CSR) policies? The CSR adage of “doing well by doing good” is normally understood in the sense that a firm can achieve higher shareholder value by balancing the goals of different stakeholders. This can be achieved in a variety of ways, including greater customer awareness (Servaes and Tamayo, 2013; Albuquerque, Koskinen, and Zhang, 2019), a longer-term planning horizon (Bénabou and Tirole, 2010), a more resilient supply chain (Hoepner et al., 2021), or better-addressed employee concerns (Edmans, 2011).

This paper provides a new rationale for “doing well by doing good.” We argue that the balancing act between shareholder interests and stakeholder interests extends beyond the corporation’s decision: it includes other industry participants as well. For example, a firm may invest on the resilience of its supply chain, but such investment may prove of limited value if its suppliers don’t do the same. Or a car manufacturer may commit to switching to all-electric vehicle production, but such move will not be sustainable unless other manufacturers follow suit.¹

We provide conditions such that value maximizing shareholders benefit from committing to a mission statement that embodies CSR. To fix ideas, we consider the specific problem of clean-technology adoption. Adoption by one firm in isolation leads to high production marginal costs, whereas adoption by multiple firms leads to all-around lower costs.² A one-shot adoption game played by shareholder-value maximizers has the nature of a prisoner’s dilemma: sticking to the legacy technology is a dominant strategy. However, we provide conditions such that the following is a Nash equilibrium: in a first stage, firms commit to a stakeholder function that places a sufficiently high weight on the adoption of a clean technology; and in the second stage firms adopt the clean technology. Our interpretation of “doing well by doing good” is that CSR helps solve a strategic dilemma, in this case a prisoner’s dilemma. In other words, by committing to departing from straight profit maximization, firms are able to effectively increase profits.

Our model suggests an additional perspective on CSR. We provide conditions such that the first stage (mission statement) is a pure coordination game: firms are better off by committing to CSR, but no firm has the incentive to unilaterally do so. This observation provides a natural and novel interpretation of strategic leadership in the CSR context: By committing to CSR, a firm effectively pulls other industry participants along, thus internalizing an externality that might otherwise lead to an inefficient equilibrium.

1. For example, there won’t be a dense network of electric charging stations unless a significant fraction of the car fleet switches to EV.

2. This can result from various factors, including learning-by-doing cost savings in the spirit of Romer (1986) in solar panel manufacturing, network benefits from a collective switch to electric vehicles (due to a dense network of charging stations or improved battery technology), or network benefits from the development of a liquid market for carbon credits.

■ **Commitment to CSR.** Whereas most prior literature has focused on CSR as a firm-level decision process, we stress the importance of strategic interaction among industry participants (e.g., rivals). We also stress the value of CSR as a commitment that influences other industry players’ behavior. This raises the question (which is not novel) of whether CSR has a real effect (as opposed to babbling at best or greenwashing at worst). We assume that firms have the ability to commit to an objective function (its “mission” or “view”) that includes profits as well as other goals.³ And we show that such commitment has the real effect of leading the industry toward a better outcome to all — including financial-value-conscious shareholders.

Since our results depend fundamentally on the commitment assumption, it is only appropriate that we discuss its validity. In his game-theory classic, Schelling (1960) elaborates at length on the conditions under which a commitment is more likely to be credible. He argues that, “to be convincing, commitments usually have to ... rest on some rationale” and that “a potent means of commitment ... is the pledge of one’s reputation.” We believe that a firm’s mission statement satisfies these requirements: It is based on a clear rationale and it does pledge the corporation’s reputation.⁴ For example, in January 2021 General Motors declared that, by 2035, it would phase out petroleum-powered cars and trucks and sell only vehicles that have zero emissions. Time will tell whether GM will live up to its promise, but it seems reasonable to assume that, if it fails to do so, then GM will suffer a significant reputation shock.⁵

While our model assumes that the firm’s mission statement is its primary source of commitment, there are certainly other devices as well. For example, the firm may hire board members and CEOs with a reputation for CSR, thus better communicating (both internally and externally) the firm’s corporate purpose (Mayer, 2021), as well as being friendly to outside investors with a preference for CSR.

Compensation pay practices that reward CSR are yet another form of commitment. Bebchuk and Tallarita (2022) report that over 50% of firms in the S&P use ESG metrics to compensate their executives, and Cohen et al. (2022) document that this preponderance is

3. There exists an economics literature that considers the possibility of committing to a value function different from firm value. In Section 2, we discuss how our paper relates and adds to this literature.

4. Azar et al. (2021) document that the top accounting firms are leading firms to lower their carbon emissions. The detail used to specify the ESG metrics identifies the specific concerns of firms and can also serve to increase the reputational commitment of firms.

5. In a similar vein, Hart and Zingales (2017) suggest that founders can guide current and future managers and boards through the company’s mission statement, though they question the fiduciary strength of mission statements in light of the business judgment rule. On the issue of fiduciary strength, we argue that mission statements should be voted by shareholders to help guide management in the pursuit of the desired goals. In its U.S. Proxy Voting Guidelines, Institutional Shareholder Services (2020) has no comment on mission statements, except perhaps to say somewhat negatively that “[e]ndorsing a set of principles may require a company to take a stand on an issue that is beyond its own control and may limit its flexibility with respect to future developments.” (page 57).

present worldwide.⁶

There is some evidence of firms formally committing to CSR-related goals. In addition to the above-mentioned GM example, one can also mention the emergence of B-corporations, that is, corporations whose objectives differ from straight profit maximization. Recently, for example, shoemaker Allbirds filed a “sustainable” initial public offering along with a commitment to follow an ESG philosophy. That said, our model is abstract enough to allow for alternatives to the firm’s mission statement as the basis of commitment to CSR. Considering the recent trends in the CSR space, one obvious alternative is the emergence of CSR-conscious active investors. According to insightia.com, the number of activist campaigns involving public environment-related demands increased from eight in each of 2020 and 2021 to 42 during the first four months of 2022. For example, in June 2021, an Exxon activist investor “successfully waged a battle to install three directors on the board of Exxon with the goal of pushing the energy giant to reduce its carbon footprint” (Phillips, 2021).⁷

There are abundant reasons to be skeptical about commitment to CSR. For example, Bebchuk and Tallarita (2020) found that commitments made by CEOs of major US corporations at the Business Roundtable had little effect. Why would we claim otherwise? First, we note that there is a significant difference between a collective commitment and the commitment made by one individual firm. The former is inevitably limited to a somewhat vague common denominator, whereas the latter can be very specific — in fact, it can be a quantitative commitment, as in the GM example considered above. Moreover, the reputation pledge mentioned by Schelling (1960) has considerably more bite at the individual corporation level rather than at the level of a “roundtable” of multiple corporations. To this we should add the very rapid growth in shareholder activism, performance pay, and the monitoring of firm compliance with respect to ESG commitments. In sum, perhaps the scope for CSR commitment was not present in the past, but we believe it is now, and increasingly so.

■ **Evidence.** While our paper is theoretical in nature, we argue that there is some evidence consistent with the idea of leadership in CSR as modeled by our game. Cao, Liang, and Zhan (2019) shows that product-market peer firms appear to adopt CSR policies after close-call CSR proposal adoption by another firm in the industry. Similarly, evidence offered by She and Zaldokas (2019) shows that environmental and social disclosures in firms’ press releases

6. We should mention that in the Bebchuk and Tallarita (2022) sample the firms using ESG metrics in compensation packages assign relatively small weights — from about 1% to 12.5% — to these pay components. However, as we show below, too large of a weight on ESG is not necessarily a good thing.

7. Dimson, Karakaş, and Li (2015) show that investor engagements tend to be relatively more successful when the firm itself has reputational concerns, which suggests that a mission statement that pledges the firm’s reputation and activist shareholders may be complementary rather than substitute factors in providing commitment power.

and analysts conference calls is correlated among peer firms and leads Environmental, Social and Governance (ESG) ratings changes.

Thematic funds that sustainable investors request from their asset managers (e.g., Triodos Bank’s wind fund) are also evidence consistent with our model. BlackRock’s site advertises thematic funds meant to capture “one-off shifts that can change an entire industry.” The portfolio companies in these funds can take the lead of the investors championing them to embrace change.

■ **Additional applications.** We consider two additional applications of our two-stage CSR game, where we change the nature of the second-stage subgame. In a second application, firms set wage rates. The externality we highlight in this application is one of industry reputation: consumers may not be aware of what each firm in the industry is doing in terms of wages (or more broadly, labor conditions), but associate every firm’s reputation to the worst industry performer. Examples may include the reputation for dealing on blood diamonds, the reputation for using forced labor in the cotton industry, or the reputation of poor working conditions in the restaurant industry. As in the first application, we prove the existence of multiple equilibria in the two-stage game, including one where firms commit to a mission statement that places positive weight on the wage rate and then set high wages in the second stage. Also as in the first application, we show that firms end up earning higher profits than they would when playing the one-shot wage-setting game, where a low wage rate is a dominant strategy.

Unlike the first two applications, where firms belong to the same industry (“horizontal” firm interaction), in a third application we consider firms located at different stages of the value chain (“vertical” firm interaction). One setting we have in mind is the investment to create a sustainable supply chain, such as when Unilever moved its Lipton tea to a 100% sustainable tea production. Another setting concerns resiliency investments, investments that increase the probability of remaining operational following a disruption in the supply chain. There is an externality in that a firm does not incorporate the benefit to connected firms associated with its own investment in a sustainable supply chain, or in the increased likelihood of survival. Perhaps the most interesting aspect of this application is that we show that opting for a CSR mission can be a dominant strategy. Intuitively, the built-in complementarities in resilience investments in the model are so significant that, independently of what the other firm does, a firm optimally opts for a mission statement that places weight on resiliency and ends up investing on resiliency beyond what a profit maximizer would do.

■ **Roadmap.** The rest of the paper is organized as follows. In the next section, we review related literature. This is particularly important in the present case as there is an extensive literature on CSR as well as a series of papers developing games where firms’ payout function

deviates from profit maximization. This asks for an explanation of the value added by our approach.

Our basic framework is developed in Section 3 together with our main application. We present two other applications in Section 4. Section 5 includes a discussion of our results. Section 6 concludes the paper.

2. Related literature

Our paper relates to an economics and finance literature focused on departures from the neoclassical paradigm of the profit-maximizing firm, a literature developed mostly, though not exclusively, in the context of CSR. Baron (2001) proposes an integrated firm strategy that extends the standard model to include private politics and CSR. Bénabou and Tirole (2010) argue that the “standard definition of CSR is that it is about sacrificing profits in the social interest,” adding that CSR emerges in response to a combination of government failure, private interests and other factors. In line with Bénabou and Tirole (2010), Hart and Zingales (2017) revisit the Friedman (1970) doctrine in the case “where shareholders are prosocial and externalities are not perfectly separable from production decisions.” Broccardo, Hart, and Zingales (2021) discuss the role of voice versus exit as strategies by socially responsible investors (see also Landier and Lovo 2022 for a model of socially responsible funds). Allen, Carletti, and Marquez (2014) and Magill, Quinzii, and Rochet (2015) take the heterogeneity of corporate forms (shareholder maximizers and stakeholder maximizers) as a given and evaluate their relative merit. Along similar lines, Tirole (2017) discusses the existence (and choice) of multiple organization types in modern economies within the context of CSR, arguing that the shareholder-primacy model is the most likely to succeed in promoting CSR changes. Finally, probably closest to our paper, Magill, Quinzii, and Rochet (2015) develop a general equilibrium model with workers, consumers and shareholders. They show that a stakeholder model, whereby the firm maximizes a sum of the surpluses of shareholders, workers and consumers. They show this leads to an Pareto optimal allocation and discuss how such an outcome can be implemented as the result of a Coasian equilibrium.

Our contribution to this strand of the literature is two-fold. First, we explore the possibility of strategic *interaction* in a CSR context. Second, we provide an explicit and formal narrative for the transition from a “Friedman firm” (that is, a classic shareholder-value maximizer as in Friedman, 1970) to a socially conscious one. Specifically, whereas in Baron (2001), for example, CSR is a means for an active shareholder to pursue his or her private agenda (which may lead to higher costs and thus differs from straight value maximization), in our framework a value-maximizing shareholder uses CSR as a means to increase shareholder value. Magill, Quinzii, and Rochet (2015) show how a stakeholder model may internalize an externality between consumers and workers. We too focus on an externality, namely across

industry players (directly competing firms or firms along the value chain). Ostrom (2015) discusses a solution to the prisoner’s dilemma that arises in common-pool problems where the agents are allowed to change the rules of the game. In her model, she adds a first stage to the prisoner’s dilemma problem where the agents can agree on a contract to split the common resource and pay a third party to enforce the contract. Our solution differs from hers in that no enforcer is needed, though a commitment mechanism is.

In parallel with the above (largely theoretical) literature on CSR, there is a series of recent empirical studies on the nature and implications of CSR. For example, Dimson, Karakas, and Li (2015) show that “success in engagements is more probable if the engaged firm has reputational concerns and higher capacity to implement changes.” Starks, Venkat, and Zhu (2020), in turn, provide evidence of sorting between shareholders and firms. Specifically, “longer-horizon investors tilt their portfolios towards firms with high-ESG profiles.” Our analysis, while primarily theoretical, has empirical implications. For example, in Section 5, we discuss the possibility of shareholder sorting as in Starks, Venkat, and Zhu (2020).

Our model is related to the industrial organization literature on strategic delegation, in particular Vickers (1985), Fershtman and Judd (1987) and Sklivas (1987).⁸ This literature shows that, in a competitive context, profit-maximizing shareholders pay CEOs to maximize a function that differs from firm profits, the specific nature of this function depending on the nature of product market competition. We complement this literature in two ways. First, we model a two-stage game with an explicit choice of objective function in the first stage. This modification is what allows us to describe the industry game as a pure coordination game and to speak to the novel aspect of strategic leadership in CSR. Second, the results on these papers and ours depend on shareholders’ ability to commit to an objective function that differs from profit maximization. We believe that in our setting commitment may be easier to affirm as it relies on investor preferences and reputational concerns with regards to her preferences. For example, the activist investor Carl Icahn bought a small stake in McDonald’s in early 2022 and nominated two new board members aimed at improving the treatment of pregnant pigs, an animal for which the investor “has a particular soft spot” (Torrella, 2022). In contrast, the previous literature models a shareholder-manager agency conflict where the possibility of secretly renegotiating the manager’s contract undermines any commitment efforts.

Finally, our paper relates to an extensive economics, strategy and management literature on leadership. In game theory and industrial organization, leadership is normally associated with the order of moves in a sequential-move game, as in, for example, the Stackelberg model (von Stackelberg, 2011). Similar to this literature, in our framework leadership is a

8. More recently, Albuquerque, Cabral, and Guedes (2019) also consider the possibility of shareholder-CEO contracts that differ from value maximization, and Morgan and Tumlinson (2019) provide an application to the provision of public goods by corporations motivated by managerial contracts that reflect investor preferences for these public goods.

commitment modeled by a sequential-move game. Different from this literature, we consider commitment to an objective function rather than commitment to an action (e.g., output or capacity level). The term leadership is often associated with the ability of a leader (e.g., a CEO) to induce other organization members to follow him or her. Dinh et al. (2014) provide a survey of the organizational behavior, whereas Hermalin (1998) follows an economics and game-theory approach. By contrast, we consider the possibility of a firm leading other industry players, either direct competitors or other firms along the value chain.

3. The model

3.1. The general framework

We model a two-stage game played by two firms, i and j . In the first stage, profit-maximizing firms choose an objective function. It is best to think of this stage as a firm committing to a mission statement, that is, an objective function that will guide the firm's decisions during the second stage. Specifically, we assume the firm's objective function is described by $\theta_i \in \{0, \bar{\theta}\}$. If $\theta_i = 0$, then the firm is a financial-value maximizer (also referred throughout the paper as a "Friedman" firm). If, by contrast, $\theta_i = \bar{\theta}$, then the firm's objective function differs from straight financial profit maximization. Specifically, we assume the firm's objective function during the second stage is given by

$$v_i(t_i, t_j; \theta_i) = \pi_i(t_i, t_j) + \theta_i f(t_i) \quad (1)$$

where t_i denotes a strategic variable chosen during the second stage, $\pi_i(t_i, t_j)$ the firm's profit, and $f(t_i)$ a component that stakeholders (other than value-maximizing shareholder) care about. Without loss of generality, below we assume that $f(t_i) = t_i$.

We study sub-game perfect Nash equilibria in pure strategies. Accordingly, we solve the game backwards, beginning with the second period. At this point, the values of θ_i and θ_j are common knowledge, that is, both players know both firms' objective function. Firm i chooses t_i to solve

$$\max_{t_i} v_i(t_i, t_j; \theta_i)$$

Note that t_i is the firm's strategy; t_j is firm i 's belief regarding firm j 's choice in the second period; and θ_i reflects firm i 's CSR commitment. Note that the value of θ_j does not enter firm i 's value function directly. However, the value of θ_j (which by now is common knowledge) does affect firm i 's belief regarding firm j 's choice t_j .

We now move back to the first stage. Anticipating a second-stage subgame equilibrium, that is, choices $\hat{t}_i(\theta_i, \theta_j)$ and $\hat{t}_j(\theta_i, \theta_j)$, firm i 's choice of θ_i in the first stage solves

$$\max_{\theta_i} \pi_i(\hat{t}_i(\theta_i, \theta_j), \hat{t}_j(\theta_i, \theta_j)) \quad (2)$$

Equation (2) makes an implicit assumption, namely that first-stage shareholders are firm-value maximizers. We make this assumption to be consistent with historical observation: firms decide whether to *become* socially responsible or not from a financial-value-maximization perspective. We also make this assumption so as to address the idea of “doing well by doing good,” namely the hypothesis that CSR is good for profit maximizers.

3.2. Clean-energy technology adoption

As a primary application of the above general CSR framework, in this section we study the adoption of a clean-energy technology (as opposed to sticking to a legacy, “dirty”, technology).⁹ Specifically, we now assume that $t_i \in \{0, 1\}$ stands for the firm’s technology choice: $t_i = 0$ corresponds to a legacy technology (dirty technology), whereas $t_i = 1$ corresponds to a green technology (clean technology). The value of θ , in turn, measures the firm’s weight on green technology adoption *beyond its implications for financial performance* (which are included in the profitability term π).

We assume that $\pi_i(t_i, t_j)$, firm i ’s profit function, results from an equilibrium where firms compete in setting quantities q_i given a linear market demand $Q = a - bp$, where by appropriate unit changes we normalize the intercept and the slope to 1.¹⁰ Marginal cost c_i is constant (with respect to q_i) but depends on the choices t_i and t_j . Specifically, we assume that if only one firm adopts the green technology, then its marginal cost of production is \bar{c} , whereas if both firms adopt the clean technology, then each firm’s marginal cost of production is $\underline{c} < \bar{c}$.

Since the relation between t_i and c_i is at the core of our clean-technology application, some notes are in order. We have in mind an externality associated with non-excludable learning by doing in the spirit of Romer (1986). One example is given by the adoption of solar panels. To the extent that the technology is subject to steep non-excludable learning by doing, we expect that the production cost of an adopter is lower the greater the number of other firms that make the same choice. Another motivating example is given by electrical vehicles. If General Motors is the only large US car manufacturer switching to electrical vehicles, then the investment in complementary assets such as charging stations or better batteries will be low. If, by contrast, many manufacturers commit to EVs, then there will be more complementary investments and as a result the production of EVs will be more efficient on a value-for-the-money basis.¹¹

9. In this regard, this section is related to Acemoglu et al. (2016), who study the transition to clean technology. They develop a competitive model and estimate the impact of taxes and subsidies to induce the transition to clean technology. Our approach differs in that we focus on the strategic interaction between industry players.

10. The analysis does not depend on the assumption of linear demand. Other demand specifications can be used requiring only that we appropriately modify the assumptions below.

11. A better network of charging stations would primarily affect consumer willingness to pay, not cost. However, the qualitative nature of the results would be similar to the cost reduction case.

Since technology choice determines marginal cost, it also affects the firms' output choices and, ultimately the firms' profits. For intermediate values of marginal cost, equilibrium profit is given by

$$\tilde{\pi}_i = \frac{1}{9} (1 + c_j - 2c_i)^2 \quad (3)$$

If, by contrast, firm j 's cost is sufficiently high, specifically if $c_j > (1 + c_i)/2$, then firm i is effectively a monopolist, earning equilibrium profits of

$$\tilde{\pi}_i = \frac{1}{4} (1 - c_i)^2 \quad (4)$$

As mentioned before, the firms' technology choices t_i determine the firms' marginal costs, which equals \bar{c} if a firm unilaterally adopts the green technology, \underline{c} if *both* firms adopt the new technology, and c if a firm sticks to the legacy technology. We make some assumptions regarding the values of c , \bar{c} and \underline{c} :

Assumption 1. $\underline{c} < c < 2\bar{c} - 1$.

The first inequality implies that, if both firms choose the clean technology, then marginal costs are lower than under the legacy technology. In other words, a social planner would choose to adopt the new technology (for simplicity, we assume zero adoption costs). The second inequality implies that, if a firm goes solo in adopting the clean technology, then its cost is so high that effectively it is priced out of the market, that is, it leaves the rival firm as a monopolist.¹² This parameter restriction describes the status quo where firms remain with the legacy technology. We make additional assumptions regarding $\bar{\theta}$ and the cost parameters:

Assumption 2. $0 < \frac{1}{4} (1 - c)^2 - \frac{1}{9} (1 - \underline{c})^2 < \bar{\theta} < \frac{1}{9} (1 - c)^2$.

These inequalities ensure that the solution to the CSR game is interior: first, we ensure that the green technology, when adopted by both firms, has lower cost than the legacy technology, but not so much lower that duopolists with \underline{c} would make more profit than a monopolist with c . Second, we ensure that social responsibility (as measured by the value of $\bar{\theta}$) is sufficiently high that a firm prefers to be a duopolist with a green technology with respect to a monopolist with the legacy technology, but not so high that a firm would prefer to completely sacrifice its duopoly profits under the legacy technology (i.e., too much "warm glow" is not allowed). These assumptions thus identify both the maximum shareholders are willing to sacrifice in terms of financial profitability, as well as the minimum preference for CSR required so as to generate an equilibrium with the implementation of the clean technology.¹³

12. Note that the second inequality is equivalent to $(1 + c)/2 < \bar{c}$.

13. Note that the inequalities in Assumption 2 induce a non-empty set. For example, suppose that $(1 - c)^2 = \frac{1}{2}$, $(1 - \underline{c})^2 = \frac{3}{4}$ and $\bar{\theta} \in [\frac{1}{24}, \frac{1}{18}]$ satisfy Assumption 2.

The proof of the next proposition and the of other results in the paper can be found in the Appendix.

Proposition 1. *There exist three different subgame-perfect equilibria of the (θ, t) two-stage game. These equilibria correspond to the following paths:*

- (a) $\theta_1 = \theta_2 = 0$, followed by $t_1 = t_2 = 0$;
- (b) $\theta_1 = \theta_2 = \bar{\theta}$, followed by $t_1 = t_2 = 1$;
- (c) $\theta_1 = \theta_2 = \bar{\theta}$, followed by $t_1 = t_2 = 0$.

Moreover, a profit-maximizing firm prefers equilibrium (b).

The three equilibria derived in Proposition 1 have an interesting interpretation in terms of the discussion regarding the nature and the effects of CSR. Equilibrium (a) corresponds to the case when firms do not engage in CSR, which, in broad strokes, might characterize the reality of the corporate world for most of the 20th century. Given that firms remain “Friedman” firms — that is, financial value maximizers — the technology-choice game has a dominant strategy, namely to stick with the legacy technology. Specifically, the technology-choice subgame has the nature of a prisoner’s dilemma: Together, firms would prefer to switch to a green technology, but individually each firm prefers to stick to the legacy technology.

Equilibrium (b) corresponds, essentially, to the idea that when firms *jointly* embrace CSR, then this choice may have real effects. It is important to stress the qualifier “jointly”. In fact, if only one firm adopts a CSR policy, then it will have no effect on the technology-choice game. The reason is that, for the firm that does not choose CSR, sticking with the legacy technology remains a dominant strategy; and even a firm that chooses CSR optimally responds to a non-adopting rival by not adopting a green technology. By contrast, if *both firms* choose $\theta_i = \bar{\theta}$, then switching to a green technology is a subgame-perfect equilibrium.

It is important to stress that we write “a” subgame-perfect equilibrium, not “the” subgame-perfect equilibrium. In fact, as equilibrium (c) in Proposition 1 suggests, even if both firms choose $\theta_i = \bar{\theta}$, there exists an equilibrium with a subgame leading to no adoption of the green technology. One might refer to this as the failure of CSR, even when CSR corresponds to collective action. From a game-theory point of view, one might appeal to Pareto optimality or forward-induction arguments, both at a theoretical and at an experimental level, to exclude this equilibrium (Schelling, 1960; Harsanyi and Selten, 1988; Cooper et al., 1990); but it certainly is a subgame-perfect Nash equilibrium. This equilibrium would also disappear if we dropped the upper bound assumption on the value of $\bar{\theta}$ in Assumption 2. We focus primarily on equilibrium (b), which seems more reasonable.

One way of rephrasing the second equilibrium in Proposition 1 is that the joint adoption of CSR effectively turns a prisoner’s dilemma game into a coordination game. Specifically,

if both firms operate as “Friedman” firms — that is, with $\theta = 0$ —, then the technology-adoption game has the nature of a prisoner’s dilemma: sticking to the legacy technology is the dominant strategy for each firm individually. By adding the initial CSR stage, where firms have the opportunity to commit to $\theta = \bar{\theta}$, we observe that there exist two equilibria (if we exclude the (c) equilibrium). These equilibria, (a) and (b), are Pareto ranked. Effectively, we have a coordination game. Specifically, there is no dominant strategy regarding the choice of CSR, rather each firm’s best response is to follow the same choice as the rival firm.

The “transformation” of a prisoner’s dilemma into a coordination game lets us introduce the idea of strategic leadership in CSR. As we have seen, the technology-adoption subgame played by Friedman firms is a prisoner’s dilemma. In this context, being a leader is of no help. In fact, a well-intentioned or a strategically-motivated leader who adopts the green technology will only find the disappointment of a rival who is grateful for the opportunity to capture market share by sticking to the legacy technology.¹⁴ By contrast, when playing the CSR coordination game there is clear scope for leadership, as there is in any perfect coordination game. Specifically, sequential choice is the most natural way to induce the “good” equilibrium of a perfect-coordination game. Firm 1 moves first and chooses $\theta = \bar{\theta}$, upon which Firm 2’s best response is to choose $\theta = \bar{\theta}$ as well, leading to joint adoption of the green technology — and to higher shareholder value.¹⁵

4. Additional applications

4.1. Labor conditions

Worker conditions, both domestically and in countries hosting suppliers, are an important component of CSR. In this section, we consider wages as the relevant dimension of worker conditions but the model can be understood more broadly in the context of any strategic variable relating to labor input such as work hours or workplace conditions. Specifically, we now assume that shareholders can commit to the objective function

$$v_i(w_i, w_j; \theta_i) = \pi_i(w_i, w_j) + \theta_i w_i. \tag{5}$$

This expression follows from (1) and is analogous to (1), with two differences. First, the second stage variable is now firm i ’s wage rate. Second, the reduced-form profit function is now different. Specifically, we consider a simple extension of the linear Cournot model of

14. Unilateral signals such as irreversible investment à la Dixit (1980) cannot help in this model since they would not affect firm’s objective function. Thus, the firm doing the investment would lose the investment and the duopoly profits.

15. In real life though, the leader will not adopt the clean technology until the follower expresses the same CSR interest, otherwise the leader will be out of the market in the second stage.

duopoly competition where market demand is given by

$$Q = \min\{w_i, w_j\} (1 - p). \quad (6)$$

The $1 - p$ term corresponds to a standard linear demand. The term, $\min\{w_i, w_j\}$, requires further explanation. The idea is that, due to consumer awareness (Servaes and Tamayo, 2013), total demand is a function of the industry's reputation for CSR. Our idea is that consumers may have difficulty identifying the specific actions of each firm. Rather, they have a general perception of the industry's CSR performance. Examples include the generalized lack of trust in the financial services industry following the 2008 subprime crisis (Lins, Servaes, and Tamayo, 2017) or the perception that the diamond industry is tainted with conflict diamonds. An alternative explanation for our assumption is that an industry's successful lobbying efforts require unanimity among all players.

The function we consider, $\min\{w_i, w_j\}$, assumes a particularly extreme form: Each firm is as bad as the worst firm in the industry. We believe our qualitative results follow with less extreme functional forms. It is important, however, that there be some complementarity between the firms' efforts in the eyes of consumers. In particular, it's of little use — in terms of market demand — if one firm unilaterally increases its wage rate. The inverse demand curve corresponding to (6) is given by

$$p = 1 - Q / \min\{w_i, w_j\} = 1 - (q_1 + q_2) / \min\{w_i, w_j\}.$$

Firm i 's profit, in turn, is given by

$$\pi_i(w_i, w_j) = q_i (1 - (q_1 + q_2) / \min\{w_i, w_j\} - w_i).$$

Firm i 's best-response is given by

$$q_i^* = \frac{1}{2} \min\{w_i, w_j\} (1 - w_i) - \frac{1}{2} q_j.$$

Solving the system of best-responses, we get

$$q_i = \frac{1}{3} \min\{w_i, w_j\} (1 + 2w_j - w_i), \quad (7)$$

$$p = \frac{1}{3} (1 + w_i + w_j), \quad (8)$$

$$\pi_i(w_i, w_j) = \frac{1}{9} \min\{w_i, w_j\} (1 + w_j - 2w_i)^2. \quad (9)$$

As per Subsection 3.1, the game unfolds over two stages. First the simultaneous, profit-maximizing choice of a value of $\theta_i \in \{0, \bar{\theta}\}$, and then, having observed (θ_i, θ_j) , the simultaneous choice of $w_i \in \{\underline{w}, \bar{w}\}$. We make a series of assumptions regarding key parameter values:

Assumption 3. *The values of \underline{w} , \bar{w} , and $\bar{\theta}$ are such that*

$$\underline{w}(1 + \bar{w} - 2\underline{w})^2 \geq \bar{w}(1 - \bar{w})^2 \geq \underline{w}(1 - \underline{w})^2, \quad (10)$$

$$\bar{w}(1 - \bar{w})^2 + \bar{\theta}\bar{w} \geq \underline{w}(1 + \bar{w} - 2\underline{w})^2 + \bar{\theta}\underline{w}, \quad (11)$$

$$\underline{w}(1 - \underline{w})^2 + \bar{\theta}\underline{w} \geq \underline{w}(1 + \underline{w} - 2\bar{w})^2 + \bar{\theta}\bar{w}. \quad (12)$$

Considering the reduced-form profit function (9), inequalities (10) imply that a Friedman firm prefers to cut wages when its rival sets a high wage but is better off when both firms set a high wage. Considering the reduced-form profit function (9) and the stakeholder value function (5), inequalities (11) and (12) imply that, by contrast with Friedman firms, a socially responsible firm prefers to set a high wage if and only if its rival sets a high wage as well. Such a profusion of conditions raises the questions of whether the set of values defined by Assumption 3 is non-empty. We answer this question in the affirmative. More generally, we can establish the following result.

Proposition 2. *There exist three different subgame-perfect equilibria of the (θ, w) two-stage game. These equilibria correspond to the following paths:*

- (a) $\theta_1 = \theta_2 = 0$, followed by $w_1 = w_2 = \underline{w}$;
- (b) $\theta_1 = \theta_2 = \bar{\theta}$, followed by $w_1 = w_2 = \bar{w}$;
- (c) $\theta_1 = \theta_2 = \bar{\theta}$, followed by $w_1 = w_2 = \underline{w}$.

Moreover, a profit-maximizing firm prefers equilibrium (b). Finally, (10)–(12) defines a positive-measure subset of the $(\bar{\theta}, \underline{w}, \bar{w})$ space.

There is a clear parallel between Proposition 2 and Proposition 1. In both cases, we discover three equilibria that have an interesting interpretation in terms of CSR. In both cases, equilibrium (b) is the more interesting (and reasonable) equilibrium. In both cases, CSR turns a prisoners’ dilemma into a coordination game. Finally, a strategic leader is a firm that in the first stage chooses a mission statement that commits to a stakeholder model. This CSR strategic leader helps solve the coordination game.

4.2. Supply chain resiliency

Unlike the first two applications, where firms belong to the same industry (“horizontal” firm interaction), our third application considers firms located at different stages of the value chain (“vertical” firm interaction). Specifically, we model a supply chain composed of two vertically integrated firms, each in its own industry. The focus of our analysis is on the resilience of supply chains. We do so by assuming that industries are subject to disruption, which we model as an exogenous shock that halts the production process. Moreover, we

assume that these shocks can be global or industry specific. Specifically, with probability $1 - \alpha$ there is no disruption in either industry; with probability $\alpha \phi$, both industries are disrupted; and with probability $\alpha(1 - \phi)$ exactly one industry is disrupted, each with probability $\alpha(1 - \phi)/2$.

This modeling approach reflects the view that disruption is sometimes limited to a given stage of the value chain, whereas at other times it extends to the entire chain. For example, the September 2000 Taiwan earthquake affected the world supply of memory chips. In terms of the computer supply chain, this can be seen as a shock to one of the stages of the chain. By contrast, the 2020 pandemic provides an example of a shock that affected entire vertical chains. Pankratz and Schiller, 2021 provide evidence that climate risks can affect global supply chains. These examples refer to physical exogenous shocks. However, disruption may also take the form of information disclosure. For example, the admission that suppliers use child labor would be an example of a shock limited to a stage of the production chain, whereas the finding that the final product requires a chemical such as asbestos that is harmful to health would affect the entire value chain. Our setting also applies to the setting of sustainable supply chains. Unilever’s decision to have 100% of its Lipton tea brand sustainably produced required a transformation of the whole supply chain that would eventually only result in increased brand name recognition and increased demand if all the different points in the supply chain were to change (see Henderson 2020). The probabilities of disruption above can be interpreted as probabilities of change.

Suppose that, by investing $c(x_i)$ dollars, where $x_i \in [0, 1]$ and $c(\cdot) > 0$, a firm can guarantee that it will operate with probability x_i in case its industry is disrupted. We refer to this as a resilience investment. For simplicity, we assume quadratic costs to investing in supply chain resilience, $c(x_i) = x_i^2/2$. An example of a resilience investment might be to build a generator so as not to be dependent on the power grid or to accumulate inventories.

Given that firm j makes a x_j investment in resilience, firm i ’s profit is given by

$$\pi_i(x_i, x_j) = \left(1 - \alpha + \frac{1}{2} \alpha(1 - \phi)(x_i + x_j) + \alpha \phi x_i x_j\right) p - \frac{1}{2} x_i^2. \quad (13)$$

The expression in large brackets corresponds to the probability that production will take place, an outcome which requires both sectors of the supply chain to operate. If there is no disruption to the process — which happens with probability $1 - \alpha$ — then it’s business as usual and resilience investments have no effect. If an idiosyncratic shock hits the sector where firm i operates — which happens with probability $\alpha(1 - \phi)/2$ — then firm i may still operate with conditional probability x_i . If instead an idiosyncratic shock hits the sector where firm j operates — which happens with probability $\alpha(1 - \phi)/2$ — then firm j may still operate with conditional probability x_j . Following an aggregate shock — which occurs with probability $\alpha \phi$ — firms i and j are in operation with conditional probability $x_i x_j$, since both firms must remain active. The value obtained from operation is $p > 0$.

Let the firm’s stakeholder value function be

$$v_i(x_i, x_j; \theta_i) = \pi_i(x_i, x_j) + \theta_i x_i. \quad (14)$$

As before, $\theta_i \in \{0, \bar{\theta}\}$ measures firm i ’s weight on outcomes that go beyond straightforward value maximization (i.e., firm i ’s concern for the “common good”). In the present context, θ_i measures how much firm i values a well-functioning supply chain (beyond what is valued by a financial optimizer). The underlying assumption is that a proper operation of the supply chain is beneficial to stakeholders (consumers, workers, and so on) beyond shareholder value.

As before, we assume that firms are originally profit maximizers and choose their mission statement. Subsequently, given the choices of θ_i and θ_j , firms choose the resilience of their production technology, formally firms choose x_i and x_j . We make the following assumption:

Assumption 4. $\alpha \phi p < 1$.

This assumption guarantees an interior solution for the optimization problem by Friedman firms. We can then establish the following result.

Proposition 3. *There exists $\tilde{\theta} > 0$ such that, if $0 < \bar{\theta} < \tilde{\theta}$ then $\theta_i = \bar{\theta}$ is a dominant strategy in the CSR game. Moreover, shareholder value is greater when $\theta_1 = \theta_2 = \bar{\theta}$ than when $\theta_1 = \theta_2 = 0$.*

From a modeling point of view, our third application differs from the first two in that the second stage corresponds to the choice of a continuous variable $x_i \in [0, 1]$. The second-stage game has the structure of the (inverse) tragedy of the commons. Due to the positive externality of the investment x_i , the Nash equilibrium of the one-shot game has firms investing at a level that is lower than the joint optimal level. A CSR mission statement implies that firm i has an added reason to increase x_i , which in turn leads the other firm also to increase the value of x_j and ultimately leads to a higher profit provided $\bar{\theta}$ is not too large.

Another important difference with respect to the first two applications is that, in the present context, the first stage game can be solved by dominant strategies (whereas in Subsections 3.2 and 4.1 it corresponds to a pure coordination game). This implies that the order of moves in the first stage is no longer relevant, and thus a CSR strategic leader is no longer necessary.

5. Discussion

In this section, we discuss various aspects of our results, including how to interpret them and what they may imply for public policy.

5.1. Relation to reputation literature

There is an interesting relation between the choice of $\bar{\theta}$ and the game theory literature on reputation (Kreps et al., 1982). In the so-called “gang-of-four” framework, Player 2 is uncertain about Player 1’s type. In certain types of games, a “normal” Player 1 may have an incentive to pool with a “crazy” Player 1 so as to induce a favorable reaction by Player 2. Player 1 does not change its utility function, rather chooses a course of action that induces Player 2 to believe that Player 1 is a “crazy” type.

The correspondence with our framework has Player 1 as firm 1’s shareholder/CEO and Player 2 as firm 2’s shareholder/CEO. A “normal” player is a Friedman shareholder, that is, one whose utility is profit maximization, whereas a “crazy” player is one whose value function includes other stakeholders’ value. The difference with respect to the reputation framework is that we do not consider the possibility of asymmetric information. Rather, we assume that players have the ability to change their utility function. To be more specific, players have the ability to choose a “mission statement,” which effectively influences their future actions as if their utility function had changed.

In spite of this difference, there is an interesting parallel between our framework and the pooling equilibrium (reputation equilibrium) in the Kreps et al.’s (1982) framework. Specifically, our preferred equilibria have a “pooling” flavor. Consider two different shareholders, one who is a profit maximizer and one who is socially conscious. In equilibrium, both take the same course of action. The socially conscious will push for a mission statement that includes CSR because that’s what his or her utility dictates. The Friedman shareholder will push for the same mission statement for a different reason: by doing so, he or she induces more favorable behavior by the rival firm and as such increases financial value.

In other words, empirically there is no way to distinguish the behavior of an “activist” shareholder who is genuinely concerned with CSR from the behavior of a Friedman shareholder who becomes an “activist” shareholder for strategic reasons. This observational equivalence is similar to a pooling equilibrium in the asymmetric information game of reputation.

5.2. Shareholder utility and the value of θ

In our basic framework, we assume that a financial value maximizer shareholder strategically adopts a CSR utility function. However, it seems reasonable to assume that many firms and shareholders are “genetically” endowed with a $\theta > 0$ utility function. This raises the question of what determines the value of θ we considered in previous sections.

In terms of our framework, the firm’s social impact (in the shareholder’s eyes) can be measured by θt_i . A further decomposition of θ may be helpful. Let $\theta \equiv \xi \chi$ where χ is the firm’s level of CSR-relevant actions (that is, the portion of t_i that is CSR relevant) and ξ is the firm’s ability to induce CSR results by its choice of χ . For example, if Google were

to increase its minimum wage from \$10 to \$15, this would likely have no real effect, for the simple reason that most of Google’s employees are high-skilled workers. In this sense, we would say that Google’s ξ is close to zero (when it comes to minimum wage, one of many components of a CSR policy). Another example is provided by Volvo. In 2020, the company announced that all new cars would have a factory speed limit of 112 miles per hour. However, speeding ranks only third in car crashes in the U.S., below driving distractions and driving with alcohol and drug impairment (Console, 2020). Again, this would be reflected in a low ξ , this time on account of the low-CSR nature of the activity in question.

In sum, the product θt reflects firm-specific and industry-specific considerations that affect the map from firm actions to actual CSR results, besides any other subjective utility by shareholders from CSR.

For simplicity, our analysis only considers two possible values of θ (0 and $\bar{\theta}$). A more general analysis would consider a range of values of θ , with 0 as a lower bound and $\bar{\theta}$ as an upper bound. The lower bound corresponds to a Friedman firm, that is, a financial value maximizer. The upper bound, in turn, corresponds to a value of θ beyond which the firm is not financially viable and thus CSR would be counter-productive (Fairhurst and Greene, 2020). Recent trends suggest that firms worldwide are moving away from the lower bound, but also that the effective values of θ are still relatively low (Bolton and Kacperczyk, 2021).

Our analysis has focused on values of $\theta > 0$. The reason is that the applications we study all involve positive externalities. Consider however the case of a negative externality: Consumer utility and therefore demand for firms’ products increases if the overall level of air pollution decreases. In this case, a preference for CSR would be equivalent to having $\theta < 0$ so that by reducing the quantity produced—and thus reducing air pollution—the firm would trade-off the loss in profits with the increase in value in θt .

5.3. Mission statement and agency issues

In the previous sections, we mentioned the firm’s mission statement in reference to the firm’s stakeholder value function (1). As Powers (2012) argues, mission statements communicate the company’s purpose to the outside world, bringing clarity as to what the firm is and is not doing. Moreover, mission statements can be an effective means of achieving the commitment we assume in our analysis (the Allbirds IPO discussed in the introduction is an example of that). In other words, our assumption that each firm chooses a value of θ in the first stage can be interpreted as modeling the firm’s choice of the mission statement it commits to.

Consistent with our analysis, Loderer et al. (2010) report that mission statements often go beyond shareholder value as the sole criterion; that is, mission statements feature positive values of θ . Similarly, King, Case, and Premo (2010) document the recent trend of adopting

“green statements”.¹⁶

In our analysis, we largely ignore agency problems involving shareholders and CEOs: our focus is on the game-theoretic dimensions of CSR policies. However, agency issues are obviously important, also concerning CSR policies. In this regard, we believe the firm’s mission statement can be an effective vehicle to align CEO and shareholders’ interests. This alignment works in two ways. First, it helps the process of sorting of shareholders and firms: When a shareholder acquires shares in firm i it effectively buys into a specific value of θ . This is related to Hart and Zingales’s (2017) effort to “reconcile” Friedman’s (1970) “duty toward shareholders” doctrine with CSR concerns. The idea is that a CEO’s duty is to follow the firm’s mission statement. To the extent that shareholders are properly sorted across mission statements, by following the firm’s mission statement, the CEO is effectively maximizing shareholders’ interests (which does not necessarily imply maximizing the firm’s financial value).¹⁷

The second direction in the shareholders-mission statement connection pertains to the role of active shareholders. Dimson, Karakaş, and Li (2015) and Flammer (2015) suggest that active shareholders play an important role in changing firm behavior. A recent case study is Carl Icahn’s activism with McDonald’s to better the treatment of pigs.¹⁸ Also, Hsu, Liang, and Matos (2022) provide evidence that state-owned companies around the world are more responsible to environmental issues. In terms of our framework, we can think of these active shareholders as a direct determinant of the firm’s mission statement (that is, the value of θ).

Related to this, we should mention that a simplifying assumption in our analysis is that firms are symmetric, both in terms of their primitive utility functions and in terms of their actions. Clearly, firm heterogeneity is an important feature of most industries, also in terms of their CSR attitude. For example, Bolton and Kacperczyk (2021) show that commitments to reduce carbon emissions vary across firms. Moreover, “companies that choose to make a commitment are the ones with lower carbon emissions to begin with.” Their interpretation of this correlation is that “companies making a commitment are the least problematic ones in terms of carbon emissions.” However, and following our discussion in Subsection 5.2, an alternative (or additional) interpretation is that of heterogeneity in θ : Some firms have higher values of θ , which in turn leads them to higher values of t (where we interpret a commitment as a choice of a future value of t).

16. The literature on mission statements (Pearce and David, 1987) has long established a correlation between the existence of a mission statement with firm performance.

17. This is our interpretation of Hart and Zingales’s (2017) interpretation of Friedman (1970).

18. Schiller (2018) and Dai, Liang, and Ng (2021) focus on other firms in the supply chain.

5.4. Leadership

For simplicity, our formal analysis was cast in terms of a two-player model. Most real-world settings, however, involve multiple firms. We believe that the qualitative nature of our results extends to this multi-player setting. This also applies to our model of leadership, which may be interpreted as a model of one single leader or instead a model of a core of leading firms. Consider for example the sustainable use of palm oil, a case documented in some detail by Henderson (2020). While Unilever took a particularly important leadership role, the European giant was accompanied by a “core” of large corporations members of the Consumer Goods Forum (CGF). The idea was that, “if these companies demanded that the commodities they bought be sustainably grown, entire industries would be forced to move in a more sustainable direction.” This is consistent with the concept of leadership we develop, albeit in a multi-player context.

5.5. Welfare analysis

Is CSR good from a social welfare point of view? Answering this question requires a definition of social welfare. A natural definition is to add the surplus from all agents in the economy. Specifically, in the clean-energy technology model, social welfare equals the sum of profits and consumer surplus. Because the equilibrium where both firms choose CSR and adopt the clean-energy technology results in lower cost and higher quantity produced — while requiring no additional investment — both profits and consumer surplus increase relative to the equilibria where both firms choose the legacy technology. It is straightforward to show that

Proposition 4. *In the clean-energy technology game, social welfare is higher in the CSR equilibrium.*

In the wage-setting model, social welfare equals the sum of profits and consumer surplus plus the portion of the wage bill that exceeds the competitive wage. Note that, in the clean-energy technology model, the hypothesis implicit in the definition of social welfare is that the firms’ costs are equal to the social cost. However, in the wage-setting model, firms set wages above the competitive level, thus transferring rents to workers. In this context, social welfare must also account for the portion of the wage bill that exceeds the competitive wage. In this context, we can prove the following result:

Proposition 5. *In the wage-setting game, if firm profits are higher when wages are high, social welfare is also higher.*

Finally, in the model of supply-chain resiliency, we do not have an explicit demand curve and as such cannot calculate consumer surplus. However, it is reasonable to assume

that consumer welfare increases as the supply chain is made more resilient. Since firm profits also increase in the CSR equilibrium, social welfare trivially increases. Overall, these results suggest that the positive role of CSR, in terms of firm profits, also extends to social welfare.

5.6. Public policy

While most of our analysis is focused on firm strategy, our framework and equilibrium results also have implications for public policy following the results in Subsection 5.5. The critical feature that leads to the strategic role played by CSR commitments is the complementarity in the second stage game. This suggests that one role for public policy is to introduce complementarities into firm actions.

Consider, for example, a tragedy-of-the-commons type subgame such as setting an upper bound on CO₂ emissions. One possible public policy design is to introduce a price subsidy that works only if all the firms in the industry reduce their pollution levels. This would lead to a subgame that shares the main features of our setup. The idea is to use firm interaction as an additional course of incentives for individual players to choose a value of t closer to the socially optimal level.

The flip-side of the subsidy instrument is the threat of regulation that affects the variable of interest (say, CO₂ emissions) say by adding costs associated with increased disclosure. The benefit from avoiding the regulation, especially if it is credible that the regulation will be implemented unless everyone becomes more CSR friendly, may be a sufficient motivator to induce firms to commit to CSR in a first-stage game.

This discussion notwithstanding, industry-wide policy instruments such as those discussed here are themselves costly say due to the financial cost of the subsidy or the cost associated with monitoring additional disclosure practices. An implementation of these initiatives would have to be confronted with more standard practices.

6. Conclusion

This paper proposes the idea that firms may choose to deviate from profit maximization — by adopting a stakeholder model via a CSR policy — and yet yield higher profits because of strategic complementarities in the industry. We illustrate this idea in three different settings. In the first two, the choice of CSR by all firms in the industry results in an equilibrium that is Pareto superior to the absence of CSR. However, there is also an equilibrium where “Friedman” firms operate. These two equilibria introduce a coordination problem that can be solved if one of the firms assumes the industry leadership to become CSR. We call this firm a strategic CSR leader. In the last setting that we study, with supply chain investment complementarities, the strategic complementarities are so strong that adopting CSR is a dominant strategy for all firms and there is no need for a strategic CSR leader.

We view mission statements as well as the hiring of board members or a CEO with a CSR reputation as ways to assert the intended specific stakeholder model to peer firms and other constituents such as supplier firms or investors. For this reason, we propose that mission statements be voted by shareholders so as to grant them greater fiduciary bite.

The paper’s main result suggests that the presence of mission statements (and of green statements) as well as the presence of green-activist investors are both more likely in industries where strategic complementarities such as those highlighted in the paper are more prominent. Corporate social responsibility, however, is not in our model a large, indiscriminate umbrella covering all the firm’s operations but rather those activities that involve such strategic complementarities.

One of the many critics of departures from profit maximization writes that

Purpose cannot solve the problem of shareholder primacy because shareholder capitalism is inherently corrupting of purpose. When purpose and shareholder value get into a boxing ring, I will bet on shareholder value every time (Davis, 2021).

Our analysis suggests that the dichotomy between purpose and shareholder value is not clear-cut. Importantly, we move away from the partial equilibrium setting of firm decision making, where traditionally CSR has been studied, and consider the industry equilibrium setting. We point out that the highlighted dichotomy may not exist in the presence of strategic complementarities in an industry.

If CSR is so good for firms and for society — as we argue can be the case — then one cannot avoid the question of why it hasn’t been adopted in the past, at least not to a great extent. One first answer is that CSR policies have indeed been adopted, that the pure Friedman firm is thing of the past. The evidence of CSR metrics in executive pay, or the sharp increase of active investing, would seem consistent with this view, at least to some extent (Cao, Liang, and Zhan, 2019). A second possible answer is that the phenomenon of “doing well by doing good,” as developed in this paper, depends crucially on the firm’s ability to commit to a mission statement. But, as illustrated by Schelling (1960) and others, the ability to commit to a course of action, namely in a corporate setting, is far from trivial and cannot be created out of thin air. In many ways, the history of civilization is a history of mutually commitments: contracts (and more generally the rule of law) may be interpreted as a form of commitment. In this sense, our message may be rephrased by stating that society is evolving in the direction of allowing mission statements to work as commitment instruments, not so much based on the rule of law but rather on corporate reputation as instrument for enforcement. Finally (and related to the previous points), we might argue that the change implied by the CSR mentality corresponds to what Henderson (2020) refers to as “architectural innovations,” innovations that break away from long standing status quo and take time to occur.

One issue that we leave for future research is the possibility that the choice of θ is continuous rather than discrete. For example, the firm may approach — or be approached — by outside investors that derive different utility over the CSR strategy. How do firms choose between the different outside investors and what is the resulting equilibrium? Presumably, an interior solution would exist to this problem since too much of a concern for CSR can tilt the balance away from profit maximization so as to decrease firm profits.

Appendix

Proof of Proposition 1: As usual, we solve the game backwards, thus ensuring the Nash equilibria we select are subgame perfect. Consider first the case when firm i chooses $\theta_i = 0$, that is, firm i is a financial value maximizer. Suppose that $t_j = 0$. Assumption 1 implies that choosing $t_i = 1$ yields zero profits, whereas choosing $t_i = 0$ yields positive profits. Suppose instead that $t_j = 1$. Assumption 1 implies that choosing $t_i = 0$ leads to monopoly profits. The first inequality in Assumption 2 implies that such monopoly profits are higher than the duopoly profits earned from choosing $t_i = 1$. Together, the above calculations imply that, for a $\theta_i = 0$ firm, $t_i = 0$ is a dominant strategy in the second stage.

Consider now the case when firm i chooses $\theta_i = \bar{\theta}$, that is, firm i maximizes a value function comprising financial value and value from choosing a green technology. The second and third inequalities in Assumption 2 imply that firm i 's best response in the second stage is $R_i(t_j) = t_j$, that is, firm i is better off by choosing the same technology as firm j . To see why, suppose that $t_j = 1$. Then $t_i = 1$ is better than $t_i = 0$ if and only if

$$\frac{1}{9}(1 - \underline{c})^2 + \bar{\theta} > \frac{1}{4}(1 - c)^2$$

which is equivalent to the second inequality in Assumption 2. Suppose instead that $t_j = 0$. Then $t_i = 0$ is better than $t_i = 1$ if and only if

$$\frac{1}{9}(1 - c)^2 > \bar{\theta}$$

which is equivalent to the third inequality in Assumption 2.

Finally, we show the three equilibria in the Proposition are indeed Nash equilibria in the meta-game played by financial value maximizers who have the ability to commit to a value of θ . Consider firm equilibrium (a). Along the equilibrium path, firm i obtains (financial) value $\frac{1}{9}(1 - c)^2$. By deviating and choosing $\theta = \bar{\theta}$, firm i is unable to induce a different t_j in the second stage, since $t_j = 0$ is a dominant strategy for a $\theta_j = 0$ firm. Since the best response to $t_j = 0$ is $t_i = 0$, regardless of the value of θ_i , we conclude that a change in θ_i does not improve firm i 's financial value.

Consider now equilibrium (b). Along the equilibrium path, firm i receives a financial payoff of $\frac{1}{9}(1 - \underline{c})^2$. By switching to $\theta_i = 0$, firm i effectively commits to $t_i = 0$, which in turn leads firm j to choose $t_j = 0$, which eventually leads to a financial payoff of $\frac{1}{9}(1 - c)^2$, which is lower than the equilibrium payoff, by the first inequality in Assumption 1.

Consider now equilibrium (c). Along the equilibrium path, firm i receives a financial payoff of $\frac{1}{9}(1 - c)^2$. By switching to $\theta_i = 0$, firm i effectively commits to $t_i = 0$, which in turn leads firm j to choose $t_j = 0$, which eventually leads to a financial payoff of $\frac{1}{9}(1 - c)^2$, the same as the equilibrium payoff.

Finally, since by Assumption 3, $\underline{c} < c$, equilibrium (b) yields the highest financial value of all three equilibria. ■

Proof of Proposition 2: As usual, we solve the game backwards, thus ensuring the Nash equilibria we select are subgame perfect. Consider first the case when $\theta_1 = \theta_2 = 0$, that is, both firms are (or remain) “Friedman” firms, that is, financial value maximizers. This case corresponds to simple Cournot competition (though with a different-than-normal demand curve). Suppose that $w_j = \underline{w}$. Then firm i ’s payoff function is strictly decreasing in w_i , thus $R_i(\underline{w}) = \underline{w}$, where R_i denotes firm i ’s best response. Suppose instead that $w_j = \bar{w}$. The first inequality in (10) implies that $R_i(\bar{w}) = \underline{w}$. It follows that $w_i = \underline{w}$ is a dominant strategy, and so the subgame where $\theta_1 = \theta_2 = 0$ leads to $w_1 = w_2 = \underline{w}$.

Consider next the case when $\theta_1 = \theta_2 = \bar{\theta}$, that is, both firms are socially responsible firms that maximize the augmented “stakeholder” value function when choosing w . Inequalities (11) imply that $R_i(w_j) = w_j$, that is, firm i ’s best response is to set the same wage level as firm j . We thus have two subgame equilibria.

Finally, suppose that $\theta_1 = 0$, whereas $\theta_2 = \bar{\theta}$. Firm 1’s best-response is the same as in the $\theta_1 = \theta_2 = 0$ subgame, that is, $w_1 = \underline{w}$ is a dominant strategy. In fact, θ_2 does not enter firm 1’s value function, only w_2 . Similarly, based on our analysis of the $\theta_1 = \theta_2 = 0$ subgame, we conclude that $R_2(w_1) = w_1$. It follows that the only equilibrium of the subgame is $w_1 = w_2 = \underline{w}$.

The three equilibria in the proposition can be derived from the discussion in the paragraphs.

The statement that firms prefer the equilibrium yielding the path $\theta_i = \bar{\theta}$ and $w_i = \bar{w}$ is equivalent to the second inequality in (10). Finally, we prove the claim that the conditions in Assumption 3 imply a positive-measure subset of \mathbb{R}^3 . The function $x(1-x)^2$ has zeros at $x = 0$ and $x = 1$ and is strictly positive and strictly concave for $x \in (0, 1)$. It follows that there exist values $1 > x_1 > x_2 > 0$ such that Condition (10) is satisfied as an equality, that is, $\bar{w}(1-\bar{w})^2 = \underline{w}(1-\underline{w})^2 = \bar{\pi}$. For these specific values of \bar{w}, \underline{w} , Condition (10) is strictly satisfied, for

$$\underline{w}(1 + \bar{w} - 2\underline{w})^2 > \underline{w}(1 + \underline{w} - 2\underline{w})^2 = \bar{w}(1 - \bar{w})^2$$

where the inequality follows from $\bar{w} > \underline{w}$ and the equality follows from our choice of \bar{w}, \underline{w} , such that $\bar{w}(1-\bar{w})^2 = \underline{w}(1-\underline{w})^2$. Next we re-write (11) as

$$\bar{\theta}(\bar{w} - \underline{w}) \geq \underline{w}(1 + \bar{w} - 2\underline{w})^2 - \bar{w}(1 - \bar{w})^2$$

Notice that the right-hand side is strictly positive:

$$\underline{w}(1 + \bar{w} - 2\underline{w})^2 - \bar{w}(1 - \bar{w})^2 > \underline{w}(1 + \underline{w} - 2\underline{w})^2 - \bar{w}(1 - \bar{w})^2 = 0$$

where the inequality follows from $\bar{w} > \underline{w}$ and the equality follows from our choice of \bar{w}, \underline{w} , such that $\bar{w}(1 - \bar{w})^2 = \underline{w}(1 - \underline{w})^2$. It follows that we can choose $\bar{\theta}$ such that (11) holds as an equality, that is,

$$\bar{\theta}(\bar{w} - \underline{w}) = \underline{w}(1 + \bar{w} - 2\underline{w})^2 - \bar{w}(1 - \bar{w})^2 \quad (15)$$

Condition (12) can be re-written as

$$\bar{\theta}(\underline{w} - \bar{w}) > \underline{w}(1 + \underline{w} - 2\bar{w})^2 - \underline{w}(1 - \underline{w})^2$$

Substituting (15) as well as $\bar{w}(1 - \bar{w})^2 = \underline{w}(1 - \underline{w})^2$, we get

$$\underline{w}(1 + \bar{w} - 2\underline{w})^2 > \underline{w}(1 + \underline{w} - 2\bar{w})^2$$

which, considering that $\underline{w}, \bar{w} \in (0, 1)$, is equivalent to $\bar{w} > \underline{w}$, which is true by construction.

To summarize, we chose values of $\underline{w}, \bar{w}, \bar{\theta}$ such that two of the conditions hold as equalities and two other ones hold strictly. By slightly increasing the value of $\bar{\theta}$, Condition (11) holds as a strict inequality; and by slightly increasing the value of \underline{w} (or decreasing \bar{w} , Condition (10) holds an equality. The result follows. ■

Proof of Proposition 3: In order to focus on sugame-perfect equilibria, we solve the game backwards, beginning with the x stage. Consider first the subgame when $\theta_1 = \theta_2 = 0$. Firm i 's best-response (optimal resilience choice x_i given that the firm j chooses x_j) is given by

$$R_i(x_j; 0) = \alpha \left(\frac{1}{2}(1 - \phi) + \phi x_j \right) p$$

where $R_i(x_j; 0)$ denotes the x_i best-response mapping of a firm with $\theta_i = 0$. It follows that the (symmetric) equilibrium of the resilience-investment subgame is given by

$$x^{00} = \frac{1}{2} \frac{\alpha(1 - \phi)p}{1 - \alpha\phi p}$$

where the 00 superscript denotes that neither firm engages in CSR (that is, neither firm has CSR in their mission statement). Consider next the subgame when $\theta_1 = \theta_2 = \bar{\theta}$. Firm i 's best-response mapping is now

$$R_i(x_j; \bar{\theta}) = \left(\frac{1}{2}\alpha(1 - \phi) + \alpha\phi x_j \right) p + \bar{\theta} \quad (16)$$

where $R_i(x_j; \bar{\theta})$ denotes the x_i best-response mapping of a firm with $\theta_i = \bar{\theta}$. The resulting equilibrium of the resilience-investment subgame is given by

$$x^{11} = \frac{\frac{1}{2}\alpha(1 - \phi)p + \bar{\theta}}{1 - \alpha\phi p}$$

where the 11 superscript denotes that both firms engage in CSR (that is, both firms have CSR in their mission statement). Finally, consider the case when (without loss of generality) $\theta_1 = \bar{\theta}$ and $\theta_2 = 0$. The best-response functions are now given by

$$\begin{aligned} R(x_2; \bar{\theta}) &= \left(\frac{1}{2} \alpha (1 - \phi) + \alpha \phi x_2 \right) p + \bar{\theta} \\ R(x_1; 0) &= \left(\frac{1}{2} \alpha (1 - \phi) + \alpha \phi x_1 \right) p \end{aligned}$$

This results in equilibrium values

$$\begin{aligned} x^{10} &= \frac{(1 + \mu) \alpha (1 - \phi) p + 2 \bar{\theta}}{2(1 - \mu^2)} \\ x^{01} &= \frac{(1 + \mu) \alpha (1 - \phi) p + 2 \mu \bar{\theta}}{2(1 - \mu^2)} \end{aligned}$$

where we define

$$\mu \equiv \alpha \phi p$$

to simplify notation. Finally, the above equilibrium values lead to equilibrium profit values

$$\begin{aligned} \pi^{00} &\equiv \pi(x^{00}, x^{00}) \\ \pi^{11} &\equiv \pi(x^{11}, x^{11}) \\ \pi^{10} &\equiv \pi(x^{10}, x^{01}) \\ \pi^{01} &\equiv \pi(x^{01}, x^{10}) \end{aligned}$$

We now consider the first stage of the game, the stage when firms choose their mission statement θ_i . Setting a high value of θ is a dominant strategy if and only if $\pi^{11} > \pi^{01}$ and $\pi^{10} > \pi^{00}$. Trivially,

$$\lim_{\theta \rightarrow 0} \pi^{11} = \lim_{\theta \rightarrow 0} \pi^{01} = \lim_{\theta \rightarrow 0} \pi^{00} = \lim_{\theta \rightarrow 0} \pi^{10}$$

Computation establishes that

$$\begin{aligned} \left. \frac{\partial(\pi^{11} - \pi^{01})}{\partial \theta} \right|_{\theta=0} &= \frac{\mu \alpha (1 - \phi) p}{2(1 - \mu)^2 (1 + \mu)} > 0 \\ \left. \frac{\partial(\pi^{10} - \pi^{00})}{\partial \theta} \right|_{\theta=0} &= \frac{\mu \alpha (1 - \phi) p}{2(1 - \mu)^2 (1 + \mu)} > 0 \\ \left. \frac{\partial(\pi^{11} - \pi^{00})}{\partial \theta} \right|_{\theta=0} &= \frac{\alpha (1 - \phi) p}{2(1 - \mu)^2} > 0 \end{aligned}$$

Finally, the result then follows from Taylor's theorem. ■

Proof of Proposition 4: For marginal cost c , in symmetric equilibria,

$$\begin{aligned}\hat{p} &= \frac{1}{3}(1 + 2c) \\ \hat{Q} &= \frac{2}{3}(1 - c) \\ \hat{\pi} &= \frac{1}{9}(1 - c)^2\end{aligned}$$

and social welfare equals

$$\begin{aligned}S &= \frac{1}{2}(1 - \hat{p})\hat{Q} + (\hat{p} - c)\hat{Q} \\ &= 2\hat{\pi}.\end{aligned}$$

The lower marginal cost of the clean-energy technology is unambiguously welfare increasing.

■

Proof of Proposition 5: The proof consists of two parts. First, we show that social welfare increases as w increases from \underline{w} to \bar{w} if and only if $\bar{w} + \underline{w} < 1$. Second, we show that, if profits increase, then it must be that $\bar{w} + \underline{w} < 1$.

In a symmetric equilibrium — that is, one where both firms choose the same wage rate — market demand, generally given by (6), becomes $Q = w(1 - p)$, whereas marginal cost is given by w (for both firms). From (7)–(8), we conclude that equilibrium price, total output, and firm profit are given by

$$\begin{aligned}\hat{p} &= \frac{1}{3}(1 + 2w) \\ \hat{Q} &= \frac{2}{3}w(1 - w) \\ \hat{\pi} &= \frac{1}{9}w(1 - w)^2\end{aligned}$$

Social welfare is the sum of the consumer surplus, firms' profits, and the excess wage bill relative to the competitive wage

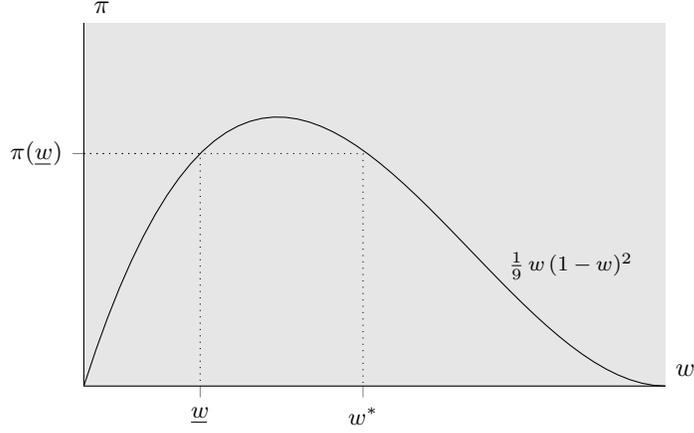

$$\begin{aligned}S &= \frac{1}{2}(1 - \hat{p})\hat{Q} + (\hat{p} - w)\hat{Q} + (w - \underline{w})\hat{Q} \\ &= \hat{Q}\left(\frac{1}{2}(1 + \hat{p}) - \underline{w}\right).\end{aligned}$$

Substituting \bar{w} and \underline{w} for w in \hat{p} and \hat{Q} and simplifying we get

$$\Delta S \equiv S|_{w=\bar{w}} - S|_{w=\underline{w}} = \frac{4}{9}(\bar{w} - \underline{w})(1 - \bar{w} - \underline{w})(1 - \underline{w})$$

Since $\bar{w} > \underline{w}$ and $\underline{w} \in (0, 1)$, $\Delta S > 0$ if and only if $\bar{w} + \underline{w} < 1$. This concludes the first part of the proof.

Figure 1
Relation between \bar{w} and \underline{w}

The function $\hat{\pi}$ is quasi-concave in $[0, 1]$, as illustrated by Figure 1. It follows that, for a given \underline{w} , Condition (10), $\bar{w}(1 - \bar{w})^2 \geq \underline{w}(1 - \underline{w})^2$, implies that $\bar{w} \in (\underline{w}, w^*)$. In other words, for a given \underline{w} , the value of \bar{w} must be greater than \underline{w} and lower than an upper bound w^* such that $w^* > \bar{w}$ and $\hat{\pi}$ is declining at w^* .

We next show that $w^* < 1 - \underline{w}$. Consider the function

$$f(x) = \frac{x(1-x)^2}{\underline{w}(1-\underline{w})^2}$$

By construction, $f(w^*) = 1$. Moreover,

$$f(1 - \underline{w}) = \frac{(1 - \underline{w})\underline{w}^2}{\underline{w}(1 - \underline{w})^2} = \frac{\underline{w}}{1 - \underline{w}} < 1$$

Since $f(\cdot)$ is decreasing in the relevant range, this implies that $w^* < 1 - \underline{w}$. This concludes the second part of the proof. ■
